Document number: IHI 0044G, current through ABI release 2019Q1.1

Date of Issue: 30<sup>th</sup> April 2019

CONTENTS 1

**CHAPTER** 

ONE

# **PREAMBLE**

# 1.1 Abstract

This document describes the processor-specific definitions for ELF for the Application Binary Interface (ABI) for the Arm architecture.

# 1.2 Keywords

Object files, file formats, linking, EABI, ELF

# 1.3 How to find the latest release of this specification or report a defect in it

Please check the Arm Developer site (https://developer.arm.com/products/software-development-tools/specifications) for a later release if your copy is more than one year old.

Please report defects in this specification to arm dot eabi at arm dot com.

## 1.4 Licence

THE TERMS OF YOUR ROYALTY FREE LIMITED LICENCE TO USE THIS ABI SPECIFICATION ARE GIVEN IN *Your licence to use this specification* (page 11) (Arm contract reference LEC-ELA-00081 V2.0). PLEASE READ THEM CAREFULLY.

BY DOWNLOADING OR OTHERWISE USING THIS SPECIFICATION, YOU AGREE TO BE BOUND BY ALL OF ITS TERMS. IF YOU DO NOT AGREE TO THIS, DO NOT DOWNLOAD OR USE THIS SPECIFICATION. THIS ABI SPECIFICATION IS PROVIDED "AS IS" WITH NO WARRANTIES (SEE *Your licence to use this specification* (page 11) FOR DETAILS).

# 1.5 Non-Confidential Proprietary Notice

This document is protected by copyright and other related rights and the practice or implementation of the information contained in this document may be protected by one or more patents or pending patent applications. No part of this document may be reproduced in any form by any means without the express prior written permission of Arm. No license, express or implied, by estoppel or otherwise to any intellectual property rights is granted by this document unless specifically stated.

Your access to the information in this document is conditional upon your acceptance that you will not use or permit others to use the information for the purposes of determining whether implementations infringe any third party patents.

THIS DOCUMENT IS PROVIDED "AS IS". ARM PROVIDES NO REPRESENTATIONS AND NO WARRANTIES, EXPRESS, IMPLIED OR STATUTORY, INCLUDING, WITHOUT LIMITATION, THE IMPLIED WARRANTIES OF MERCHANTABILITY, SATISFACTORY QUALITY, NON-INFRINGEMENT OR FITNESS FOR A PARTICULAR PURPOSE WITH RESPECT TO THE DOCUMENT. For the avoidance of doubt, Arm makes no representation with respect to, and has undertaken no analysis to identify or understand the scope and content of, patents, copyrights, trade secrets, or other rights.

This document may include technical inaccuracies or typographical errors.

TO THE EXTENT NOT PROHIBITED BY LAW, IN NO EVENT WILL ARM BE LIABLE FOR ANY DAMAGES, INCLUDING WITHOUT LIMITATION ANY DIRECT, INDIRECT, SPECIAL, INCIDENTAL, PUNITIVE, OR CONSEQUENTIAL DAMAGES, HOWEVER CAUSED AND REGARDLESS OF THE THEORY OF LIABILITY, ARISING OUT OF ANY USE OF THIS DOCUMENT, EVEN IF ARM HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

This document consists solely of commercial items. You shall be responsible for ensuring that any use, duplication or disclosure of this document complies fully with any relevant export laws and regulations to assure that this document or any portion thereof is not exported, directly or indirectly, in violation of such export laws. Use of the word "partner" in reference to Arm's customers is not intended to create or refer to any partnership relationship with any other company. Arm may make changes to this document at any time and without notice.

If any of the provisions contained in these terms conflict with any of the provisions of any click through or signed written agreement covering this document with Arm, then the click through or signed written agreement prevails over and supersedes the conflicting provisions of these terms. This document may be translated into other languages for convenience, and you agree that if there is any conflict between the English version of this document and any translation, the terms of the English version of the Agreement shall prevail.

# **ABOUT THIS DOCUMENT**

# 2.1 Change control

# 2.1.1 Current status and anticipated changes

The following support level definitions are used by the Arm ABI specifications:

Release Arm considers this specification to have enough implementations, which have received sufficient testing, to verify that it is correct. The details of these criteria are dependent on the scale and complexity of the change over previous versions: small, simple changes might only require one implementation, but more complex changes require multiple independent implementations, which have been rigorously tested for cross-compatibility. Arm anticipates that future changes to this specification will be limited to typographical corrections, clarifications and compatible extensions.

**Beta** Arm considers this specification to be complete, but existing implementations do not meet the requirements for confidence in its release quality. Arm may need to make incompatible changes if issues emerge from its implementation.

**Alpha** The content of this specification is a draft, and Arm considers the likelihood of future incompatible changes to be significant.

All content in this document is at the **Release** quality level.

This document supersedes Arm ELF, Document Number SWS ESPC 0003 B-02.

# 2.1.2 Change history

Issue	Date	Ву	Change
1.0	24th March 2005	RE	First public release.
1.01	5th July 2005	LS	Defined in Section Types (page 22), Special Sections (page 23) SHT_ARM_PREEMPTMAP; corrected the erroneous value of SHT_ARM_ATTRIBUTES.
1.02	6th January 2006	RE	Minor correction to definition of e_entry ( <i>ELF Header</i> (page 20)). Clarified restrictions on local symbol removal in relocatable files ( <i>Symbol names</i> (page 27)). Clarified the definition of R_ARM_RELATIVE when S = 0 ( <i>Dynamic relocations</i> (page 42)). Added material describing architecture compatibility for executable files ( <i>Platform architecture compatibility data</i> (page 46)).

Continued on next page

Table 2.1 – continued from previous page

Issue	Date	By	Change
1.03	5th May 2006	RE	Clarified that bit[0] of [e_entry] con-
1.05	3th May 2000	ILL	trols the instruction set selection
			on entry. Added rules governing
			SHF_MERGE optimizations (Merging
			of objects in sections with SHF_MERGE
			(page 23)). Added material describ-
			ing initial addends for REL-type relo-
			cations (Addends and PC-bias compen-
			sation (page 29)).
1.04	25th January 2007	RE	In Relocation (page 29) cor-
			rected the definition of
			R ARM ALU (PC SB) Gn NC,
			R ARM THM PC8,
			R ARM THM PC12, and
			R_ARM_THM_ALU_PREL_11_0.
			Added a table of 32-bit thumb relo-
			cations. In Relocation types (page 30)
			and Relocations for thread-local
			storage (page 41), added new relo-
			cations to support an experimental
			Linux TLS addressing model In Plat-
			form architecture compatibility data
			(page 46) reduced the field masked by
			PT ARM ARCHEXT ARCHMSK to 8
			bits (no current value exceeds 4 bits).
1.05	25th September 2007	RE	Correct definition of Pa in Relocation
			types (page 30) (the bit-mask was in-
			correct). Corrected spelling of TLS re-
			locations in <i>Relocations for thread-local</i>
			storage (page 41).
۸	25th Ostobor 2007	I.C	
A	25th October 2007	LS	Document renumbered (formerly
			GENC-003538 v1.05).
В	2nd April 2008	RE	Corrected error in Table 4-14
			(page 37) where instructions
			for R_ARM_THM_PC12 and
			R_ARM_THM_ALU_PREL_11_0 had
			been transposed.
С	10th October 2008	RE	In Static Arm relocations (page 33),
		LS	specified which relocations are per-
			mitted to generate veneers corrupting
			ip. In <i>Dynamic relocations</i> (page 42)
			specified the meaning of dynamic
			meaning of dynamic relocations relo-
			incaming of dynamic relocations left-
			cations R_ARM_TLS_DTPMOD32 and
			cations R_ARM_TLS_DTPMOD32 and R_ARM_TLS_TPOFF32 when the sym-
			cations R_ARM_TLS_DTPMOD32 and R_ARM_TLS_TPOFF32 when the symbol is NULL. Reserved vendor-specific
			cations R_ARM_TLS_DTPMOD32 and R_ARM_TLS_TPOFF32 when the symbol is NULL. Reserved vendor-specific section numbers and names to the
			cations R_ARM_TLS_DTPMOD32 and R_ARM_TLS_TPOFF32 when the symbol is NULL. Reserved vendor-specific

Table 2.1 – continued from previous page

Issue	Date	Ву	Change
D	28th October 2009	LS	Added http://infocenter.arm.com/ references to the recently published [AR-
			MARM <sup>1</sup> ] and the [ARMv5ARM <sup>2</sup> ]; in
			Static Thumb32 relocations (page 37)
			cross-referenced permitted veneer-
			generation. In Static Thumb16
			relocations (page 37), Table 4-13,
			Static Thumb-16 Relocations (page 37),
			extended R_ARM_THM_PC8 to ADR
			as well as LDR(literal). Updated and
			tidied Platform architecture compatibil-
			ity data (page 46) and added Platform
			architecture compatibility data (ABI
			format) (page 48) as a proposal for
			recording executable file attributes.

2.1. Change control 7

Table 2.1 – continued from previous page

Issue	Date	Ву	Change
E	30th November 2012	AC	In ELF Header (page 20) Table 4-2
_	30111101011111012	110	(page 21), added ELF header e flags
			to indicate floating point PCS con-
			formance and a mask for legacy
			bits. In <i>Relocation</i> (page 29), stan-
			dardized instruction descriptions to
			use Arm ARM terminology. In
			Addends and PC-bias compensation
			(page 29), clarified initial addend
			formulation for MOVW/MOVT and
			R ARM THM PC8. In Relocation types
			(page 30) Table 4-9 (page 31), re-
			served relocation 140 for a specific fu-
			ture use. In Static Arm relocations
			(page 33), <i>Table 4-12</i> (page 35), added
			entries for MOVW and MOVT; in sub-
			section Call and Jump Relocations:
			grouped R ARM THM CALL with the
			other Thumb relocations, and in the fi-
			nal paragraph changed the behaviour
			of jump relocations to unresolved
			weak references to be implementation-
			defined rather than undefined. In
			Static Arm relocations (page 33), Ta-
			ble 4-13 (page 37), added Over-
			flow column. In Static Thumb32
			relocations (page 37), Table 4-14
			(page 37), corrected Result Mask for
			R_ARM_THM_PC12; added <i>Table 4-15</i>
			(page 38) Thumb relocation actions by
			instruction type; corrected final para-
			graph to clarify the cross-reference to
			call and jump relocations. In <i>Reloca-</i>
			tion types (page 30), Static Thumb32
			relocations (page 37), Proxy gener-
			ating relocations (page 40), added
			R_ARM_THM_GOT_BREL12. In Dy-
			namic relocations (page 42), Table 4-
			18 (page 42), clarified the wording for
			R_ARM_RELATIVE. In Platform archi-
			tecture compatibility data (ABI format)
			(page 48), corrected off-by-one error
			in size of array.

Table 2.1 – continued from previous page

Issue	Date	Ву	Change
F	24th November 2015	CR	Relocation types (page 30), Table 4-9 (page 31), Changed the subdivisions within the reserved/unallocated relocation space (136-255). Renumbered R_ARM_IRELATIVE from 140 to 160 (the number agreed with stakeholders; publication as 140 was incorrect). In Static Arm relocations (page 33) Table 4-11 (page 34), removed incorrect overflow check on R_ARM_MOVT_ABS, R_ARM_MOVT_PREL and R_ARM_MOVT_BREL. Clarified in Relocation types (page 30) that relocation expression values are computed mod 2^32. In Relocation (page 29), added R_ARM_THM_ALU_ABS_Gn[_NC] relocations. In Section Attribute Flags (page 22), added SHF_ARM_NOREAD processor specific section attribute flag.
2018Q4	21st December 2018	OS	In Section Attribute Flags (page 22), renamed SHF_ARM_NOREAD to SHF_ARM_PURECODE, relaxed definition.  In Private relocations (page 43), expanded private relocation space to 32 relocations, and clarified relationship with EI_OSABI.  In ELF Identification (page 21), added EI_OSABI value for ELFOSABI_ARM_FDPIC.

# 2.3 Terms and abbreviations

The ABI for the Arm Architecture uses the following terms and abbreviations.

**AAPCS** Procedure Call Standard for the Arm Architecture

**ABI** Application Binary Interface:

- 1. The specifications to which an executable must conform in order to execute in a specific execution environment. For example, the Linux ABI for the Arm Architecture.
- 2. A particular aspect of the specifications to which independently produced relocatable files must conform in order to be statically linkable and executable. For example, the C++ ABI for the Arm Architecture, the Run-time ABI for the Arm Architecture, the C Library ABI for the Arm Architecture.

**AEABI** (Embedded) ABI for the Arm architecture (this ABI...)

**Arm-based** ... based on the Arm architecture ...

**core registers** The general purpose registers visible in the Arm architecture's programmer's model, typically r0-r12, SP, LR, PC, and CPSR.

**EABI** An ABI suited to the needs of embedded, and deeply embedded (sometimes called free standing), applications.

- **Q-o-I** Quality of Implementation a quality, behavior, functionality, or mechanism not required by this standard, but which might be provided by systems conforming to it. Q-o-I is often used to describe the tool-chain-specific means by which a standard requirement is met.
- **VFP** The Arm architecture's Floating Point architecture and instruction set. In this ABI, this abbreviation includes all floating point variants regardless of whether or not vector (V) mode is supported.

# 2.4 Your licence to use this specification

IMPORTANT: THIS IS A LEGAL AGREEMENT ("LICENCE") BETWEEN YOU (AN INDIVIDUAL OR SINGLE ENTITY WHO IS RECEIVING THIS DOCUMENT DIRECTLY FROM ARM LIMITED) ("LICENSEE") AND ARM LIMITED ("ARM") FOR THE SPECIFICATION DEFINED IMMEDIATELY BELOW. BY DOWNLOADING OR OTHERWISE USING IT, YOU AGREE TO BE BOUND BY ALL OF THE TERMS OF THIS LICENCE. IF YOU DO NOT AGREE TO THIS, DO NOT DOWNLOAD OR USE THIS SPECIFICATION.

"Specification" means, and is limited to, the version of the specification for the Applications Binary Interface for the Arm Architecture comprised in this document. Notwithstanding the foregoing, "Specification" shall not include (i) the implementation of other published specifications referenced in this Specification; (ii) any enabling technologies that may be necessary to make or use any product or portion thereof that complies with this Specification, but are not themselves expressly set forth in this Specification (e.g. compiler front ends, code generators, back ends, libraries or other compiler, assembler or linker technologies; validation or debug software or hardware; applications, operating system or driver software; RISC architecture; processor microarchitecture); (iii) maskworks and physical layouts of integrated circuit designs; or (iv) RTL or other high level representations of integrated circuit designs.

Use, copying or disclosure by the US Government is subject to the restrictions set out in subparagraph (c)(1)(ii) of the Rights in Technical Data and Computer Software clause at DFARS 252.227-7013 or subparagraphs (c)(1) and (2) of the Commercial Computer Software – Restricted Rights at 48 C.F.R. 52.227-19, as applicable.

This Specification is owned by Arm or its licensors and is protected by copyright laws and international copyright treaties as well as other intellectual property laws and treaties. The Specification is licensed not sold.

1. Subject to the provisions of Clauses 2 and 3, Arm hereby grants to LICENSEE, under any intellectual property that is (i) owned or freely licensable by Arm without payment to unaffiliated third parties

and (ii) either embodied in the Specification or Necessary to copy or implement an applications binary interface compliant with this Specification, a perpetual, non-exclusive, non-transferable, fully paid, worldwide limited licence (without the right to sublicense) to use and copy this Specification solely for the purpose of developing, having developed, manufacturing, having manufactured, offering to sell, selling, supplying or otherwise distributing products which comply with the Specification.

- 2. THIS SPECIFICATION IS PROVIDED "AS IS" WITH NO WARRANTIES EXPRESS, IMPLIED OR STATUTORY, INCLUDING BUT NOT LIMITED TO ANY WARRANTY OF SATISFACTORY QUALITY, MERCHANTABILITY, NONINFRINGEMENT OR FITNESS FOR A PARTICULAR PURPOSE. THE SPECIFICATION MAY INCLUDE ERRORS. Arm RESERVES THE RIGHT TO INCORPORATE MODIFICATIONS TO THE SPECIFICATION IN LATER REVISIONS OF IT, AND TO MAKE IMPROVEMENTS OR CHANGES IN THE SPECIFICATION OR THE PRODUCTS OR TECHNOLOGIES DESCRIBED THEREIN AT ANY TIME.
- 3. This Licence shall immediately terminate and shall be unavailable to LICENSEE if LICENSEE or any party affiliated to LICENSEE asserts any patents against Arm, Arm affiliates, third parties who have a valid licence from Arm for the Specification, or any customers or distributors of any of them based upon a claim that a LICENSEE (or LICENSEE affiliate) patent is Necessary to implement the Specification. In this Licence; (i) "affiliate" means any entity controlling, controlled by or under common control with a party (in fact or in law, via voting securities, management control or otherwise) and "affiliated" shall be construed accordingly; (ii) "assert" means to allege infringement in legal or administrative proceedings, or proceedings before any other competent trade, arbitral or international authority; (iii) "Necessary" means with respect to any claims of any patent, those claims which, without the appropriate permission of the patent owner, will be infringed when implementing the Specification because no alternative, commercially reasonable, non-infringing way of implementing the Specification is known; and (iv) English law and the jurisdiction of the English courts shall apply to all aspects of this Licence, its interpretation and enforcement. The total liability of Arm and any of its suppliers and licensors under or in relation to this Licence shall be limited to the greater of the amount actually paid by LICENSEE for the Specification or US\$10.00. The limitations, exclusions and disclaimers in this Licence shall apply to the maximum extent allowed by applicable law.

Arm Contract reference LEC-ELA-00081 V2.0 AB/LS (9 March 2005)

# 2.5 Acknowledgements

This specification has been developed with the active support of the following organizations. In alphabetical order: Arm, CodeSourcery, Intel, Metrowerks, Montavista, Nexus Electronics, PalmSource, Symbian, Texas Instruments, and Wind River.

#### **CHAPTER**

# **THREE**

## **SCOPE**

This specification provides the processor-specific definitions required by ELF [SCO-ELF<sup>10</sup>] for Arm based systems.

The ELF specification is part of the larger System V ABI specification where it forms chapters 4 and 5. However, the specification can be used in isolation as a generic object and executable format.

*Platform Standards* (page 14) of this document covers ELF related matters that are platform specific. Most of this material is related to the Base Platform ABI.

*Object Files* (page 20) and *Program Loading and Dynamic Linking* (page 46) of this document are structured to correspond to chapters 4 and 5 of the ELF specification. Specifically:

- Object Files (page 20) covers object files and relocations
- Program Loading and Dynamic Linking (page 46) covers program loading and dynamic linking.

There are several drafts of the ELF specification on the SCO web site. This specification is based on the December 2003 draft, which was the most recent stable draft at the time this specification was developed.

<sup>10</sup> http://www.sco.com/developers/gabi/

# **PLATFORM STANDARDS**

# 4.1 Base Platform ABI (BPABI)

The BPABI is an abstract platform standard. Platforms conforming to the BPABI can generally share a common toolchain with minimal post-processing requirements.

# 4.1.1 Symbol Versioning

The BPABI uses the GNU-extended Solaris symbol versioning mechanism [SYM-VER<sup>11</sup>].

Concrete data structure descriptions can be found in /usr/include/sys/link.h (Solaris), /usr/include/elf.h (Linux), in the Linux base specifications [LSB<sup>12</sup>], and in Drepper's paper [SYM-VER<sup>13</sup>]. Drepper provides more detail than the summary here.

An object or executable file using symbol versioning shall set the EI\_OSABI field in the ELF header to ELFOSABI\_ARM\_AEABI or some other appropriate operating-system specific value.

#### **Symbol versioning sections**

Symbol versioning adds three sections to an executable file (under the SVr4 ABI these are included in the RO program segment). Each section can be located via a DT\_xxx entry in the file's dynamic section.

- The version definitions section. This section defines:
  - The symbol versions associated with symbols exported from this executable file.
  - The version of the file itself.
- The version section.

This section extends the dynamic symbol table with an extra Elf32\_Half field for each symbol. The N<sup>th</sup> entry gives the index in the virtual table of versions (described below) of the version associated with the N<sup>th</sup> symbol.

• The versions needed section.

This section describes the versions referred to by symbols not defined in this executable file. Each entry names a DSO and points to a list of versions needed from it. In effect this represents FROM DSO IMPORT Ver1, Ver2, . . . . This section provides a record of the symbol bindings used by the static linker when the executable file was created.

In standard ELF style, both the version definitions section and the versions needed section identify (via the sh\_link field in their section headers) a string table section (often .dynstr) containing the textual values they refer to.

<sup>11</sup> http://www.akkadia.org/drepper/symbol-versioning

<sup>12</sup> http://refspecs.linuxfoundation.org/lsb.shtml

<sup>&</sup>lt;sup>13</sup> http://www.akkadia.org/drepper/symbol-versioning

#### The (virtual) table of versions

When an executable file uses symbol versioning there is also a virtual table of versions. This is not represented in the file (there is no corresponding file component). It contains a row for each distinct version defined by, and needed by, this file.

Each version defined, and each version needed, by this file carries its row index in this virtual table, so the table can be constructed on demand. Indexes 2, 3, 4, and so on, are local to this file. Indexes 0 and 1 have predefined global meanings, as do indexes with the top bit (0x8000) set.

#### **Locating symbol versioning sections**

The version definition section can be located via keys in the dynamic section, as follows.

DT_VERDEF (0x6FFFFFFC)	address
DT_VERDEFNUM (0x6FFFFFFD)	count

This key pair identifies the head and length, of a list of version definitions exported from this executable file. The list is not contiguous – each member points to its successor.

The versions needed section can be located via keys in the dynamic section, as follows.

DT_VERNEED (0x6FFFFFFE)	address
DT_VERNEEDNUM (0x6FFFFFFF)	count

This key pair identifies the head and length of a list of needed versions. Each list member identifies a DSO imported from, and points to a sub-list of versions used by symbols imported from that DSO at the time this executable file was created by the static linker. Neither list need be contiguous – each member points to its successor.

The version section can be located via a key in the dynamic section, as follows.

DT_VERSYM	(0x6FFFFFF0)	address

The version section adds a field to each dynamic symbol that identifies the version of that symbol's definition, or the version of that symbol needed to satisfy that reference. The number of entries must be same as the number of entries in the dynamic symbol table identified by DT\_SYMTAB and DT\_HASH (and by the Arm-specific tag DT\_ARM\_SYMTABSZ).

#### Version definition section

The version definition section has the name .XXX\_verdef and the section type  $SHT_XXX_verdef$  (the names vary but the section type -0x6FFFFFFD – is the same for Solaris and Linux). Its  $sh_link$  field identifies the string table section (often .dynstr) it refers to.

The version definition section defines a set of versions exported from this file and the successor relationships among them.

Each version has a textual name, and two versions are the same if their names compare equal. Textual names are represented by offsets into the associated string table section. Names that must be processed during dynamic linking are also hashed using the standard ELF hash function [SCO-ELF<sup>14</sup>].

Each version definition is linked to the next version definition via it vd\_next field which contains the byte offset from the start of this version definition to the start of the next one. Zero marks the end of the list.

<sup>14</sup> http://www.sco.com/developers/gabi/

Each symbol exported from this shared object refers, via an index in the version section, to one of these version definitions. If bit 15 of the index is set, the symbol is hidden from static binding because it has an old version.

During static linking against this shared object, an undefined symbol can only match an identically named STB\_GLOBAL definition which refers to one of these version definitions via an index with bit 15 clear.

Each top-level version definition links via its vd\_aux field to a list of version names. Each link contains the byte offset between the start of the structure containing it and the start of the structure linked to. Zero marks the end of the list. The first member of the list names the latest version, hashed in the version definition's vd\_hash field. Subsequent members name predecessor versions, but these are irrelevant to both static and dynamic linking.

#### Symbol version section

The symbol version section has the name .XXX\_versym and the section type  $SHT_XXX_versym$  (the names vary but the section type -0x6FFFFFFF - is the same for Solaris and Linux).

The symbol version section is a table of ELF32\_Half values. The N<sup>th</sup> entry in the section corresponds to the N<sup>th</sup> symbol in the dynamic symbol table.

- 0 if the symbol is local to this executable file.
- 1 if the symbol is undefined and unbound (to be bound dynamically), or if the symbol is defined and names the version of the executable file (usually a shared object) itself.
- The index (> 1) of the corresponding version definition, or version needed, in the virtual table of versions (described in *Symbol versioning sections* (page 14)).

This is the same value as is stored in the vd\_ndx field of a version definition structure and the vna\_other field of a version needed auxiliary structure.

Bit 15 of the index is set to denote that this is an old version of the symbol. Such symbols are not used during static binding, but may be linked to during dynamic linking.

#### **Versions needed section**

The versions needed section has the name .XXX\_verneed and the section type  $SHT_XXX_verneed$  (the names vary but the section type - 0x6FFFFFFE - is the same for Solaris and Linux). Its  $sh_link$  field identifies the string table section (often .dynstr) it refers to.

The versions needed section contains a list of needed DSOs, and the symbol versions needed from them.

Within each version needed structure, the vn\_file field is the offset in the associated string section of the SONAME of the needed DSO, and the vn\_next field contains the byte offset from the start of this version needed structure to the start of its successor.

Each version needed structure links to a sub-list of needed versions via a byte offset to the start of the first member in its vn\_aux field. In effect this represents FROM DSO IMPORT Ver1, Ver2, ...

Each version needed auxiliary structure contains its index in the virtual table of versions in its vna\_other field. The vna\_name field contains the offset in the associated string table of the name of the required version.

#### 4.1.2 Symbol Pre-emption in DLLs

Under SVr4, symbol pre-emption occurs at dynamic link time, controlled by the dynamic linker, so there is nothing to encode in a DSO.

In the DLL-creating tool flow, pre-emption happens off line and must be recorded in a BPABI executable file in a form that can be conveniently processed by a post linker. If there is to be any pre-emption when a process is created, what to do must be recorded in the platform executable produced by the post linker.

#### **Pre-emption Map Format**

Static preemption data is recorded in a special section in the object file. The map is recorded in the dynamic section with the tag DT\_ARM\_PREEMPTMAP, which contains the virtual address of the map.

In the section view, the pre-emption map special section is called .ARM.preemptmap. It has type SHT\_ARM\_PREEMPTMAP. In common with other sections that refer to a string table, its sh\_link field contains the section index of an associated string table.

The map contains a sequence of entries of the form:

```
Elf32_Word count // Count of pre-empted definitions following
Elf32_Word symbol-name // Offset in the associated string table
Elf32_Word pre-empting-DLL // Offset in the associated string table
Elf32_Word pre-empted-DLL // Offset in the associated string table
... //
```

The map is terminated by a count of zero.

If count is non-zero, the next two words identify the name of the symbol being pre-empted and the name (SONAME) of the executable file providing the pre-empting definition. This structure is followed by count words each of which identifies the SONAME of an executable file whose definition of symbol-name is pre-empted.

Symbol-name is the offset in the associated string table section of a NUL-terminated byte string (NTBS) that names a symbol defined in a dynamic symbol table. This value must not be 0.

Each of pre-empting-DLL and pre-empted-DLL is an offset in the associated string table section of an NTBS naming a DLL. The name used is the shared object name (SONAME) cited by DT\_NEEDED dynamic tags. The root executable file does not have a SONAME, so its name is encoded as 0.

# 4.1.3 PLT Sequences and Usage Models

#### Symbols for which a PLT entry must be generated

A PLT entry implements a long-branch to a destination outside of this executable file. In general, the static linker knows only the name of the destination. It does not know its address or instruction-set state. Such a location is called an imported location or imported symbol.

Some targets (specifically SVr4-based DSOs) also require functions exported from an executable file to have PLT entries. In effect, exported functions are treated as if they were imported, so that their definitions can be overridden (pre-empted) at dynamic link time.

A linker must generate a PLT entry for each candidate symbol cited by a BL-class relocation directive.

- For an SVr4-based DSO, each STB\_GLOBAL symbol with STV\_DEFAULT visibility is a candidate.
- For all other platforms conforming to this ABI, only non-WEAK, not hidden (by STV\_HIDDEN), undefined, STB\_GLOBAL symbols are candidates.

**Note:** When targeting DLL-based and bare platforms, relocations that cite WEAK undefined symbols must be performed by the static linker using the appropriate NULL value of the relocation. No WEAK undefined symbols are copied to the dynamic symbol table. WEAK definitions may be copied to the dynamic table, but it is Q-o-I whether a dynamic linker will take any account of the WEAK attribute. In contrast, SVr4-based platforms process WEAK at dynamic link time.

#### Overview of PLT entry code generation

A PLT entry must be able to branch any distance to either instruction-set state. The span and state are fixed when the executable is linked dynamically. A PLT entry must therefore end with code similar to the

following.

Arm V5 and later	Arm V4T	
LDR pc, Somewhere	LDR ip, Somewhere	
	BX ip	
Somewhere: DCD Destination		

**Note:** There is no merit in making the final step PC-relative. A location must be written at dynamic link time and at that time the target address must be known [even if dynamic linking is performed off line]. Similarly, it is generally pointless trying to construct a PLT entry entirely in 16-bit Thumb instructions. Even with the overhead of an inline Thumb-to-Arm state change, an Arm-state entry is usually smaller and always faster.

The table below summarizes the code generation variants a static linker must support. PLT refers to the read-only component of the veneer and PLTGOT to the corresponding writable function pointer.

Table 3-1, PLT code generation options

Platform family	Neither ROM replaceable nor	ROM replaceable, or PLT is free
,	free of dynamic relocations	of dynamic relocations
DLL-like, single address space (Palm OS-like)	PLT code loads a function pointer from the PLT, for example:  LDR pc, LX, LX DCD R_ARM_GLOB_DAT(X)	PLT code loads the PLTGOT entry SB-relative ( <i>DLL-like</i> , <i>single address space</i> , <i>PLT linkage</i> (page 50))
DLL-like, multiple virtual ad-	PLT code loads a function	PLT code loads the PLTGOT en-
dress spaces (Symbian OS-like)	pointer from the PLT (code and	try via an address constant in
	dynamic relocation as shown	the PLT (DLL-like, multiple vir-
	above).	tual address space, PLT linkage
		(page 50))
SVr4-like (Linux-like)	Not applicable, but as above if it	PLT code loads the PLTGOT en-
	were.	try PC-relative (SVr4 DSO-like
		PLT linkage (page 51)).

Following subsections present specimen Arm code sequences appropriate to the right hand column. In each case simplification to the direct (no PLTGOT) case is shown in the left hand column.

#### Note also that:

- In each case we assume Arm architecture V5 or later, and omit the 4-byte Thumb-to-Arm prelude that is needed to support Thumb-state callers.
- Under Arm architecture V4T, in the two DLL cases shown in the first column above, the final LDR pc, . . . , can be replaced by LDR ip, . . . ; BX ip.
- In the case of SVr4 linkage there is an additional constraint to support incremental dynamic linking, namely that ip must address the corresponding PLTGOT entry. This constraint is most easily met under architecture V4T by requiring DSOs to be entered in Arm state (but more complex solutions are possible).
- Other platforms are free to impose the same constraint if they support incremental dynamic linking.

#### **PLT** relocation

A post linker may need to distinguish PLTGOT-generating relocations from GOT-generating ones.

If the static linker were generating a relocatable ELF file it would naturally generate the PLT into its own section (.plt, say), subject to relocations from a corresponding relocation section (.rel.plt say). No other GOT-generating relocations can occur in .rel.plt, so that section would contain all the PLTGOT-generating relocations. By the usual collation rules of static linking, in a subsequent executable file-producing link step those relocations would end up in a contiguous sub-range of the dynamic relocation section.

The ELF standard requires that the GOT-generating relocations of the PLT are emitted into a contiguous sub-range of the dynamic relocation section. That sub-range is denoted by the standard tags DT\_JMPREL and DT\_PLTRELSZ. The type of relocations (REL or RELA) is stored in the DT\_PLTREL tag.

## **OBJECT FILES**

# 5.1 Introduction

# 5.1.1 Registered Vendor Names

Various symbols and names may require a vendor-specific name to avoid the potential for name-space conflicts. The list of currently registered vendors and their preferred short-hand name is given in *Table 4-1, Registered Vendors* (page 20). Tools developers not listed are requested to co-ordinate with Arm to avoid the potential for conflicts.

Name Vendor Analog Devices ADI Reserved for use by Arm C Language Extensions. acle Reserved to the ABI for the Arm Architecture (EABI pseudo-vendor) aeabi Reserved to private experiments by the Xyz vendor. Guaranteed not to clash with any AnonXyz registered vendor name. anonXyz ARM Arm Ltd (Note: the company, not the processor). C++ ABI pseudo-vendor сха Freescale Semiconductor Inc. FSL Green Hills Systems GHS GNU compilers and tools (Free Software Foundation) gnu IAR Systems iar ImageCraft Creations Inc (ImageCraft C Compiler) icc Intel Corporation intel Intel Xscale ixs The LLVM/Clang projects 11vm **PSI** PalmSource Inc. ΤI Reserved for use in thread-local storage routines. tls Wind River Systems. WRS

Table 5.1: Registered Vendors

To register a vendor prefix with Arm, please E-mail your request to arm.eabi at arm.com.

# 5.2 ELF Header

The ELF header provides a number of fields that assist in interpretation of the file. Most of these are specified in the base standard. The following fields have Arm-specific meanings.

- **e\_type** There are currently no Arm-specific object file types. All values between ET\_LOPROC and ET\_HIPROC are reserved to future revisions of this specification.
- e machine An object file conforming to this specification must have the value EM\_ARM (40, 0x28).
- **e\_entry** The value stored in this field is treated like any other code pointer. Specifically, if bit[0] is 0b1 then the entry point contains Thumb code; while bit[1:0] = 0b00 implies that the entry point contains Arm code. The combination bit[1:0] = 0b10 is reserved.

The base ELF specification requires this field to be zero if an application does not have an entry point. Nonetheless, some applications may require an entry point of zero (for example, via the reset vector).

A platform standard may specify that an executable file always has an entry point, in which case e entry specifies that entry point, even if zero.

**e\_flags** The processor-specific flags are shown in *Table 4-2, Arm-specific e\_flags* (page 21). Unallocated bits, and bits allocated in previous versions of this specification, are reserved to future revisions of this specification.

Table 4-2, Arm-specific e\_flags

Value	Meaning	
EF_ARM_ABIMASK	This masks an 8-bit version number, the version of the ABI to which this	
(0xFF000000)	ELF file conforms. This ABI is version 5. A value of 0 denotes unknown	
(current version is	conformance.	
0x05000000)		
EF_ARM_BE8	The ELF file contains BE-8 code, suitable for execution on an Arm Architec-	
(0x00800000)	ture v6 processor. This flag must only be set on an executable file.	
EF_ARM_GCCMASK	Legacy code (ABI version 4 and earlier) generated by gcc-arm-xxx might	
(0x00400FFF)	use these bits.	
EF_ARM_ABI_FLOAT_HARD	Set in executable file headers (e_type = ET_EXEC or ET_DYN) to note	
(0x00000400) (ABI	that the executable file was built to conform to the hardware floating-point	
version 5 and later)	procedure-call standard.	
	Compatible with legacy (pre version 5) gcc use as EF_ARM_VFP_FLOAT.	
EF_ARM_ABI_FLOAT_SOFT	Set in executable file headers (e_type = ET_EXEC or ET_DYN) to note	
(0x00000200) (ABI	explicitly that the executable file was built to conform to the soft-	
version 5 and later)	ware floating-point procedure-call standard (the base standard). If	
	both EF_ARM_ABI_FLOAT_XXXX bits are clear, conformance to the base	
	procedure-call standard is implied.	
	Compatible with legacy (pre version 5) gcc use as EF_ARM_SOFT_FLOAT.	

#### 5.2.1 ELF Identification

The 16-byte ELF identification (e\_ident) provides information on how to interpret the file itself. The following values shall be used on Arm systems

- EI CLASS An Arm ELF file shall contain ELFCLASS32 objects.
- **EI\_DATA** This field may be either ELFDATA2LSB or ELFDATA2MSB. The choice will be governed by the default data order in the execution environment. On an Architecture v6 processor operating in BE8 mode all instructions are in little-endian format. An executable image suitable for operation in this mode will have EF\_ARM\_BE8 set in the e\_flags field.
- **EI\_OSABI** This field shall be zero unless the file uses objects that have flags which have OS-specific meanings (for example, it makes use of a section index in the range SHN\_LOOS through SHN\_HIOS). Processor-specific values for this field are defined in *Table 4-3 Arm-specific EI\_OSABI values* (page 22).

5.2. ELF Header 21

Table 5.2: Table 4-3 Arm-specific EI OSABI values

Value	Meaning
ELFOS-	The object contains symbol versioning extensions as described in <i>Symbol</i>
ABI_ARM_AEABI	Versioning (page 14).
(64)	
ELFOS-	The object uses relocations in the private range, with semantics defined by
ABI_ARM_FDPIC	[FDPIC <sup>15</sup> ].
(65)	

# 5.3 Sections

# 5.3.1 Special Section Indexes

There are no processor-specific special section indexes defined. All processor-specific values are reserved to future revisions of this specification.

# 5.3.2 Section Types

The defined processor-specific section types are listed in *Table 4-4, Processor specific section types* (page 22). All other processor-specific values are reserved to future revisions of this specification.

Table 5.3: Table 4-4, Processor specific section types

Name	Value	Comment
SHT_ARM_EXIDX	0x70000001	Exception Index table
SHT_ARM_PREEMPTMAP	0x70000002	BPABI DLL dynamic linking pre-emption map
SHT_ARM_ATTRIBUTES	0x70000003	Object file compatibility attributes
SHT_ARM_DEBUGOVERLAY	0x70000004	See [DBGOVL] for details.
SHT_ARM_OVERLAYSECTION	0x70000005	

Pointers in sections of types SHT\_INIT\_ARRAY, SHT\_PREINIT\_ARRAY and SHT\_FINI\_ARRAY shall be expressed either as absolute values or relative to the address of the pointer; the choice is platform defined. In object files the relocation type R\_ARM\_TARGET1 may be used to indicate this target-specific relocation processing.

SHT\_ARM\_EXIDX marks a section containing index information for exception unwinding. See EHABI for details.

SHT\_ARM\_PREEMPTMAP marks a section containing a BPABI DLL dynamic linking pre-emption map. See *Pre-emption Map Format* (page 17).

SHT\_ARM\_ATTRIBUTES marks a section containing object compatibility attributes. See *Build Attributes* (page 24).

### 5.3.3 Section Attribute Flags

The defined processor-specific section attribute flags are listed in *Table 4-5, Processor specific section attribute flags* (page 22). All other processor-specific values are reserved to future revisions of this specification.

Table 5.4: Table 4-5, Processor specific section attribute flags

Name	Value	Comment
SHF_ARM_PURECODE	0x20000000	The contents of this section contains only program in-
		structions and no program data

<sup>15</sup> https://github.com/mickael-guene/fdpic\_doc

If any section contained by a segment does not have the SHF\_ARM\_PURECODE section flag set, the PF\_R segment flag must be set in the program header for the segment. If all sections contained by a segment have the SHF\_ARM\_PURECODE section flag, a linker may optionally clear the PF\_R segment flag in the program header of the segment, to signal to the runtime that the program does not rely on being able to read that segment.

#### Merging of objects in sections with SHF\_MERGE

In a section with the SHF\_MERGE flag set, duplicate used objects may be merged and unused objects may be removed. An object is used if:

- A relocation directive addresses the object via the section symbol with a suitable addend to point to the object.
- A relocation directive addresses a symbol within the section. The used object is the one addressed by the symbol irrespective of the addend used.

# 5.3.4 Special Sections

Table 4-6, Arm special sections (page 23) lists the special sections defined by this ABI.

Table 4 6, Arm special sections

Name	Туре	Attributes
.ARM.exidx*	SHT_ARM_EXIDX	SHF_ALLOC + SHF_LINK_ORDER
.ARM.extab*	SHT_PROGBITS	SHF_ALLOC
.ARM.preemptmap	SHT_ARM_PREEMPTMAP	SHF_ALLOC
.ARM.attributes	SHT_ARM_ATTRIBUTES	none
.ARM.debug_overlay	SHT_ARM_DEBUGOVERLAY	none
.ARM.overlay_table	SHT_ARM_OVERLAYSECTION	See [DBGOVL] for details

Names beginning .ARM.exidx name sections containing index entries for section unwinding. Names beginning .ARM.extab name sections containing exception unwinding information. See [EHABI] for details.

.ARM.preemptmap names a section that contains a BPABI DLL dynamic linking pre-emption map. See *Pre-emption Map Format* (page 17).

. ARM. attributes names a section that contains build attributes. See Build Attributes (page 24).

.ARM.debug\_overlay and .ARM.overlay\_table name sections used by the Debugging Overlaid Programs ABI extension described in [DBGOVL].

Additional special sections may be required by some platforms standards.

# 5.3.5 Section Alignment

There is no minimum alignment required for a section. However, sections containing thumb code must be at least 16-bit aligned and sections containing Arm code must be at least 32-bit aligned.

Platform standards may set a limit on the maximum alignment that they can guarantee (normally the page size).

5.3. Sections 23

#### 5.3.6 Build Attributes

Build attributes are encoded in a section of type SHT\_ARM\_ATTRIBUTES, and name .ARM.attributes.

The content of the section is a stream of bytes. Numbers other than subsection sizes are encoded numbers using unsigned LEB128 encoding (ULEB128), DWARF-3 style [GDWARF<sup>16</sup>].

Attributes are divided into sub-sections. Each subsection is prefixed by the name of the vendor. There is one subsection that is defined by the "aeabi" pseudo-vendor and contains general information about compatibility of the object file. Attributes defined in vendor-specific sections are private to the vendor. In a conforming object file the information recorded in a vendor-specific section may be safely ignored if it is not understood.

Most build attributes naturally apply to a whole translation unit; however, others might apply more naturally to a section or to a function (symbol of type STT\_FUNC). To permit precise description of attributes the syntax permits three granularities of translation at which an attribute can be expressed.

A section inherits the attributes of the file of which it is a component. A symbol definition inherits the attributes of the section in which it is defined. Attributes that cannot apply to the smaller entity are not inherited.

**Note:** Attributes that naturally apply to a translation unit may, nonetheless, end up applying to a section if sections from distinct relocatable files are combined into a single relocatable file by "partial linking". Similar exceptions may occur at the function level through use of #pragma and other Q-o-I tool chain behavior.

Explicit per-section and per-symbol data should be generated only when it cannot be implied by this inheritance. Being explicit is more verbose, and the explicit options are intended to capture exceptions.

#### **Syntactic structure**

The overall syntactic structure of an attributes section is:

*Format-version* describes the format of the following data. It is a single byte (not ULEB128). This is version 'A' (0x41). This field exists to permit future incompatible changes in format.

Section-length is a 4-byte unsigned integer in the byte order of the ELF file. It contains the length of the vendor-specific data, including the length field itself, the vendor name string and its terminating NUL byte, and the following attribute data. That is, it is the offset from the start of this vendor subsection to the start of the next vendor subsection.

*Vendor-name* is a NUL-terminated byte string in the style of a C string. Vendor names begining "Anon" or "anon" are reserved to unregistered private use.

**Note:** In general, a .ARM. attributes section in a relocatable file will contain a vendor subsection from the "aeabi" pseudo vendor and, optionally, one from the generating tool chain (e.g. "Arm", "gnu", "WRS", etc) as listed in *Registered Vendor Names* (page 20).

It is required that:

<sup>16</sup> http://dwarfstd.org/Dwarf3Std.php

- Attributes that record facts about the compatibility of this relocatable file with other relocatable files are recorded in the public "aeabi" subsection.
- Attributes meaningful only to the producer are recorded in the private vendor subsection. These must not affect compatibility between relocatable files unless that is recorded in the "aeabi" subsection using generic compatibility tags.
- Generic compatibility tags must record a "safe" approximation. A tool chain may record more precise information that only that tool chain comprehends.

**Note:** The intent is that a "foreign" tool chain should not mistakenly link incompatible binary files. The consequence is that a foreign tool chain might sometimes refuse to link files that could be safely linked, because their incompatibility has been crudely approximated.

There are no constraints on the order or number of vendor subsections. A consumer can collect the public ("aeabi") attributes in a single pass over the section, then all of its private data in a second pass.

A vendor-attributes subsection may contain any number of sub-subsections. Each records attributes relating to:

- The whole relocatable file. These sub-subsections contain just a list of attributes.
- A set of sections within the relocatable file. These sub-subsections contain a list of section numbers followed by a list of attributes.
- A set of (defined) symbols in the relocatable file. These sub-subsections contain a list of symbol numbers followed by a list of attributes.

A sub-subsection starts with a tag that identifies the type of the sub-subsection (file, section, or symbol), followed by a 4-byte unsigned integer size in the byte-order of the ELF file. The size is the total size of the sub-subsection including the tag, the size itself, and the sub-subsection content.

Both section indexes and defined symbol indexes are non-zero, so a NUL byte ends a string and a list of indexes.

There are no constraints on the order or number of sub-subsections in a vendor subsection. A consumer that needs the data in inheritance order can obtain the file attributes, the section-related attributes, and the symbol-related attributes, by making three passes over the subsection.

A public attribute is encoded as a tag (non zero, ULEB128-encoded followed by a value. A public value is either an enumeration constant (ULEB128-encoded) or a NUL-terminated string.

Some examples of tags and their argument sorts include:

```
Tag_CPU_raw_name <string> -- 0x04, "ML692000"
Tag_CPU_name <string> -- 0x05, "Arm946E-S"
Tag_PCS_R9_use <uleb128> -- 0x0E, 0x01 (R9 used as SB)
Tag_PCS_config <uleb128> -- 0x0D, 0x03 (Linux DSO [/fpic] configuration)
```

#### Top level structure tags

The following tags are defined globally:

```
Tag_File, (=1), uleb128:byte-size
Tag_Section, (=2), uleb128:byte-size
Tag_Symbol, (=3), uleb128:byte-size
```

# 5.4 String Table

There are no processor-specific extensions to the string table.

5.4. String Table 25

# 5.5 Symbol Table

There are no processor-specific symbol types or symbol bindings. All processor-specific values are reserved to future revisions of this specification.

# 5.5.1 Weak Symbols

There are two forms of weak symbol:

- A weak reference This is denoted by st\_shndx=SHN\_UNDEF, ELF32\_ST\_BIND()=STB\_WEAK.
- A weak definition This is denoted by st\_shndx!=SHN\_UNDEF, ELF32\_ST\_BIND()=STB\_WEAK.

#### **Weak References**

Libraries are not searched to resolve weak references. It is not an error for a weak reference to remain unsatisfied.

During linking, the value of an undefined weak reference is:

- Zero if the relocation type is absolute
- The address of the place if the relocation type is pc-relative
- The nominal base address if the relocation type is base-relative.

See Relocation (page 29) for further details.

#### **Weak Definitions**

A weak definition does not change the rules by which object files are selected from libraries. However, if a link set contains both a weak definition and a non-weak definition, the non-weak definition will always be used.

#### 5.5.2 Symbol Types

All code symbols exported from an object file (symbols with binding STB\_GLOBAL) shall have type STT\_FUNC.

All extern data objects shall have type STT\_OBJECT. No STB\_GLOBAL data symbol shall have type STT\_FUNC.

The type of an undefined symbol shall be STT\_NOTYPE or the type of its expected definition.

The type of any other symbol defined in an executable section can be STT\_NOTYPE. The linker is only required to provide interworking support for symbols of type STT\_FUNC (interworking for untyped symbols must be encoded directly in the object file).

## 5.5.3 Symbol Values

In addition to the normal rules for symbol values the following rules shall also apply to symbols of type STT\_FUNC:

- If the symbol addresses an Arm instruction, its value is the address of the instruction (in a relocatable object, the offset of the instruction from the start of the section containing it).
- If the symbol addresses a Thumb instruction, its value is the address of the instruction with bit zero set (in a relocatable object, the section offset with bit zero set).
- For the purposes of relocation the value used shall be the address of the instruction (st\_value & ~1).

**Note:** This allows a linker to distinguish Arm and Thumb code symbols without having to refer to the map. An Arm symbol will always have an even value, while a Thumb symbol will always have an odd value. However, a linker should strip the discriminating bit from the value before using it for relocation.

## 5.5.4 Symbol names

A symbol that names a C or assembly language entity should have the name of that entity. For example, a C function called calculate generates a symbol called calculate (not \_calculate).

Symbol names are case sensitive and are matched exactly by linkers.

Any symbol with binding STB\_LOCAL may be removed from an object and replaced with an offset from another symbol in the same section under the following conditions:

- The original symbol and replacement symbol are not of type STT\_FUNC, or both symbols are of type STT FUNC and describe code of the same execution type (either both Arm or both Thumb).
- All relocations referring to the symbol can accommodate the adjustment in the addend field (it is permitted to convert a REL type relocation to a RELA type relocation).
- The symbol is not described by the debug information.
- The symbol is not a mapping symbol.
- The resulting object, or image, is not required to preserve accurate symbol information to permit decompilation or other post-linking optimization techniques.
- If the symbol labels an object in a section with the SHF\_MERGE flag set, the relocation using symbol may be changed to use the section symbol only if the initial addend of the relocation is zero.

No tool is required to perform the above transformations; an object consumer must be prepared to do this itself if it might find the additional symbols confusing.

**Note:** Multiple conventions exist for the names of compiler temporary symbols (for example, ARMCC uses Lxxx.yyy, while GNU uses .Lxxx).

## Reserved symbol names

The following symbols are reserved to this and future revisions of this specification:

- Local symbols (STB\_LOCAL) beginning with '\$'
- Global symbols (STB GLOBAL, STB WEAK) beginning with 'aeabi' (double 'at start).
- Global symbols (STB GLOBAL, STB WEAK) ending with any of '\$\$base', '\$\$length' or '\$\$limit'
- Symbols matching the pattern \${Ven|other}\${AA|AT|TA|TT}\${I|L|S}[\$PI]\$\$symbol
- Local symbols (STB LOCAL) beginning with 'Lib\$Request\$\$' or 'BuildAttributes\$\$'
- Symbols beginning with '\$Sub\$\$' or '\$Super\$\$'

Note that global symbols beginning with '\_vendor\_' (double '\_' at start), where vendor is listed in *Registered Vendor Names* (page 20), Registered Vendor Names, are reserved to the named vendor for the purpose of providing vendor-specific tool-chain support functions.

Conventions for reserved symbols for which support is not required by this ABI are described in AP-PENDIX A, Conventions for Symbols containing \$.

5.5. Symbol Table 27

# 5.5.5 Mapping symbols

A section of an ELF file can contain a mixture of Arm code, Thumb code and data.

There are inline transitions between code and data at literal pool boundaries. There can also be inline transitions between Arm code and Thumb code, for example in Arm-Thumb inter-working veneers.

Linkers, and potentially other tools, need to map images correctly (for example, to support byte swapping to produce a BE-8 image from a BE-32 object file). To support this, a number of symbols, termed mapping symbols appear in the symbol table to denote the start of a sequence of bytes of the appropriate type. All mapping symbols have type STT\_NOTYPE and binding STB\_LOCAL. The st\_size field is unused and must be zero.

The mapping symbols are defined in *Table 4-7, Mapping symbols* (page 28). It is an error for a relocation to reference a mapping symbol. Two forms of mapping symbol are supported:

• a short form, that uses a dollar character and a single letter denoting the class. This form can be used when an object producer creates mapping symbols automatically, and minimizes symbol table space \* a longer form, where the short form is extended with a period and then any sequence of characters that are legal for a symbol. This form can be used when assembler files have to be annotated manually and the assembler does not support multiple definitions of symbols.

Table 4-7, Mapping symbols

Name	Meaning
	Start of a sequence of Arm instructions
\$a	
\$a. <any></any>	
	Start of a sequence of data items (for example, a literal pool)
\$d	•
\$d. <any></any>	
	Start of a sequence of Thumb instructions
\$t	
\$t. <any></any>	
ψι. \απγ /	

#### Section-relative mapping symbols

Mapping symbols defined in a section define a sequence of half-open address intervals that cover the address range of the section. Each interval starts at the address defined by the mapping symbol, and continues up to, but not including, the address defined by the next (in address order) mapping symbol or the end of the section. A section must have a mapping symbol defined at the beginning of the section; however, if the section contains only data then the mapping symbol may be omitted.

#### Absolute mapping symbols

Mapping symbols are no-longer required for the absolute section. The equivalent information is now conveyed by the type of the absolute symbol.

## 5.6 Relocation

Relocation information is used by linkers in order to bind symbols and addresses that could not be determined when the initial object was generated. In these descriptions, references in the style LDR(1) refer to the Armv5 Architecture Reference Manual [Armv5 ARM] while those in the style LDR(immediate, Thumb) give the corresponding reference to the Arm Architecture Reference Manual Arm v7-A and Arm v7-R edition [ARMARM<sup>17</sup>].

#### 5.6.1 Relocation codes

The relocation codes for Arm are divided into four categories:

- · Mandatory relocations that must be supported by all static linkers
- · Platform-specific relocations that are required for specific virtual platforms
- Private relocations that are guaranteed never to be allocated in future revisions of this specification, but which must never be used in portable object files.
- Unallocated relocations that are reserved for use in future revisions of this specification.

#### Addends and PC-bias compensation

A binary file may use REL or RELA relocations or a mixture of the two (but multiple relocations for the same address must use only one type). If the relocation is pc-relative then compensation for the PC bias (the PC value is 8 bytes ahead of the executing instruction in Arm state and 4 bytes in Thumb state) must be encoded in the relocation by the object producer.

Unless specified otherwise, the initial addend for REL type relocations is formed according to the following rules.

- If the place is subject to a data-type relocation, the initial value in the place is sign-extended to 32 bits
- If the place contains an instruction, the immediate field for the instruction is extracted from it and used as the initial addend. If the instruction is a SUB, or an LDR/STR type instruction with the 'up' bit clear, then the initial addend is formed by negating the unsigned immediate value encoded in the instruction.

Some examples are shown in Table 4-8, Examples of REL format initial addends (page 29).

Table 4-8, Examples of REL format initial addends

Instruction	Relocation	Encoding	Initial Addend
SUB R0, R1, #1020	R_ARM_ALU_PC_G0	0xe2410fff	-1020
LDR R0, [R2, #16]	R_ARM_LDR_PC_G2	0xe59f0010	16
BL .	R_ARM_THM_CALL	0xf7ff, 0xfffe	-4
DCB 0xf0	R_ARM_ABS8	0xf0	-16

If the initial addend cannot be encoded in the space available then a RELA format relocation must be used.

There are three special cases for forming the initial addend of REL-type relocations where the immediate field cannot normally hold small signed integers:

5.6. Relocation 29

<sup>17</sup> https://developer.arm.com/docs/ddi0406/c/arm-architecture-reference-manual-armv7-a-and-armv7-r-edition

- For relocations processing MOVW and MOVT instructions (in both Arm and Thumb state), the initial addend is formed by interpreting the 16-bit literal field of the instruction as a 16-bit signed value in the range -32768 <= A < 32768. The interpretation is the same whether the relocated place contains a MOVW instruction or a MOVT instruction.
- For R\_ARM\_THM\_JUMP6 the initial addend is formed by the formula (((imm + 4) & 0x7f) 4), where imm is the concatenation of bit[9]:bit[7:3]:'0' from the Thumb CBZ or CBNZ instruction being relocated.
- For R\_ARM\_THM\_PC8 the initial addend is formed by the formula (((imm + 4) & 0x3ff) 4), where imm is the 32-bit value encoded in the 8-bit place, as defined in the LDR(3)/LDR(literal) Thumb instructions section of the [ARMARM<sup>18</sup>].

#### **Relocation types**

Table 4-9, Relocation codes (page 31) lists the relocation codes for Arm. The table shows:

- The code which is stored in the ELF32\_R\_TYPE component of the r\_info field.
- The mnemonic name for the relocation.
- The type of the relocation. This field substantially divides the relocations into Static and Dynamic relocations. Static relocations are processed by a static linker; they are normally either fully resolved or used to produce dynamic relocations for processing by a post-linking step or a dynamic loader. A well formed image will have no static relocations after static linking is complete, so a post-linker or dynamic loader will normally only have to deal with dynamic relocations. This field is also used to describe deprecated, obsolete, private and unallocated relocation codes. Deprecated codes should not be generated by fully conforming toolchains; however it is recognized that there may be substantial existing code that makes use of these forms, so it is expected that a linker may well be required to handle them at this time. Obsolete codes should not be used, and it is believed that there is little or no common use of these values. All unallocated codes are reserved for future allocation.
- The class of the relocation describes the type of place being relocated: these are Data, Arm, Thumb16 and Thumb32 (32-bit long-format instructions). A special class of Miscellaneous is used when the operation is not a simple mathematical expression.
- The operation field describes how the symbol and addend are processed by the relocation code. It does not describe how the addend is formed (for a REL type relocation), what overflow checking is done, or how the value is written back into the place: this information is given in subsequent sections. In all cases, relocation expression values are computed mod 2 ^ 32.

The following nomenclature is used for the operation:

- S (when used on its own) is the address of the symbol.
- A is the addend for the relocation.
- P is the address of the place being relocated (derived from r offset).
- Pa is the adjusted address of the place being relocated, defined as (P & 0xFFFFFFFC).
- T is 1 if the target symbol S has type STT\_FUNC and the symbol addresses a Thumb instruction; it is 0 otherwise.
- B(S) is the addressing origin of the output segment defining the symbol S. The origin is not required to be the base address of the segment. This value must always be word-aligned.
- GOT\_ORG is the addressing origin of the Global Offset Table (the indirection table for imported data addresses). This value must always be word-aligned. See *Proxy generating relocations* (page 40).
- GOT(S) is the address of the GOT entry for the symbol S.

Table 5.5 - continued from previous page

#### **Static Data relocations**

Except as indicated in *Table 4-10, Static Data relocations with non-standard size or processing* (page 33) all static data relocations have size 4, alignment 1 and write the full 32-bit result to the place; there is thus no need for overflow checking.

The overflow ranges for R\_ARM\_ABS16 and R\_ARM\_ABS8 permit either signed or unsigned results. It is therefore not possible to detect an unsigned value that has underflowed by a small amount, or a signed value that has overflowed by a small amount.

Table 4-10, Static Data relocations with non-standard size or processing

Code	Name	Size	REL Addend	Overflow
5	R_ARM_ABS16	2	sign_extend(P[16:0])	$-32768 \le X \le 65535$
8	R_ARM_ABS8	1	sign_extend(P[8:0])	$-128 \le X \le 255$
42	R_ARM_PREL31	4	sign_extend(P[30:0])	31-bit 2's complement

#### **Static Arm relocations**

The relocations that can modify fields of an Arm instruction are listed in *Table 4-11, Static Arm instruction relocations* (page 34). All relocations in this class relocate a 32-bit aligned Arm instruction by modifying part of the instruction. In most cases the modification is to change the offset, but in some cases the opcode itself may be changed (for example, an ADD may be converted to a SUB and vice-versa). In the table:

• X is the 32-bit result of normal relocation processing

5.6. Relocation 33

• Gn is a mask operation that is instruction dependent. See Group Relocations below for rules on how the mask is formed for each case.

The formation of the initial addend in a REL type relocation for the various instruction classes is described in *Table 4-12, Arm relocation actions by instruction type* (page 35). Insn modification describes how the

32-bit result X is written back to the instruction; Result\_Mask is the value of X after the masking operation described in Table 4 11 has been applied.

### **Call and Jump relocations**

There is one relocation (R\_ARM\_CALL) for unconditional function call instructions (BLX and BL with the condition field set to 0xe), and one for jump instructions (R\_ARM\_JUMP24). The principal difference between the two relocation values is the handling of Arm/Thumb inter-working: on Arm architecture 5 and above, an instruction relocated by R\_ARM\_CALL that calls a function that is entered in Thumb state may be relocated by changing the instruction to BLX; an instruction relocated by R\_ARM\_JUMP24 must use a veneer to effect the transition to Thumb state. Conditional function call instructions (BL<cond>) must be relocated using R\_ARM\_JUMP24.

A linker may use a veneer (a sequence of instructions) to implement the relocated branch if the relocation is one of R\_ARM\_PC24, R\_ARM\_CALL, R\_ARM\_JUMP24, (or, in Thumb state, R\_ARM\_THM\_CALL, R\_ARM\_THM\_JUMP24, or R\_ARM\_THM\_JUMP19) and:

- The target symbol has type STT\_FUNC
- Or, the target symbol and relocated place are in separate sections input to the linker

In all other cases a linker shall diagnose an error if relocation cannot be effected without a veneer. A linker generated veneer may corrupt register r12 (IP) and the condition flags, but must preserve all other registers. On M-profile processors a veneer may also assume the presence of a stack with at least 8 bytes (2 words) of memory. Linker veneers may be needed for a number of reasons, including, but not limited to:

- Target is outside the addressable span of the branch instruction (+/- 32Mb)
- Target address and execution state will not be known until run time, or the address might be pre-empted

In some systems indirect calls may also use veneers in order to support dynamic linkage while preserving pointer equivalence. On platforms that do not support dynamic pre-emption of symbols an unresolved weak reference to a symbol relocated by R\_ARM\_CALL (or, in Thumb state, R\_ARM\_THM\_CALL) shall be treated as a jump to the next instruction (the call becomes a no-op). The behaviour of R\_ARM\_JUMP24 and static Thumb jump relocations in these conditions is implementation-defined.

#### **Group relocations**

Relocation codes 4 and 57-83 are intended to relocate sequences of instructions that generate a single address. They are encoded to extract the maximum flexibility from the Arm ADD- and SUB-immediate instructions without need to determine during linking the full sequence being used. The relocations operate by performing the basic relocation calculation and then partitioning the result into a set of groups of bits that can be statically determined. All processing for the formation of the groups is done on the absolute value of X; the sign of X is used to determine whether ADD or SUB instructions are used, or, if the sequence concludes with a load/store operation, the setting of the U bit (bit 23) in the instruction.

A group,  $G_n$ , is formed by examining the residual value,  $Y_n$ , after the bits for group  $G_{n-1}$  have been masked off. Processing for group  $G_0$  starts with the absolute value of X. For ALU-type relocations a group is formed by determining the most significant bit (MSB) in the residual and selecting the smallest constant  $K_n$  such that

$$MSB(Y_n) & (255 << 2K_n) != 0,$$

except that if  $Y_n$  is 0, then  $K_n$  is 0. The value  $G_n$  is then

$$Y_n & (255 << 2K_n),$$

and the residual,  $Y_{n+1}$ , for the next group is

$$Y_n \& \sim G_n$$
.

Note that if  $Y_n$  is 0, then  $G_n$  will also be 0.

For group relocations that access memory the residual value is examined in its entirety (i.e. after the appropriate sequence of ALU groups have been removed): if the relocation has not overflowed, then the residual for such an instruction will always be a valid offset for the indicated type of memory access.

Overflow checking is always performed on the highest-numbered group in a sequence. For ALU-type relocations the result has overflowed if Yn+1 is not zero. For memory access relocations the result has overflowed if the residual is not a valid offset for the type of memory access.

**Note:** The unchecked (\_NC) group relocations all include processing of the Thumb bit of a symbol. However, the memory forms of group relocations (eg R\_ARM\_LDR\_G0) ignore this bit. Therefore the use of the memory forms with symbols of type STT\_FUNC is unpredictable.

#### Static Thumb16 relocations

Relocations for 16-bit thumb instructions are shown in *Table 4-13*, *Static Thumb-16 Relocations* (page 37). In general the addressing range of these relocations is too small for them to reference external symbols and they are documented here for completeness. A linker is not required to generate trampoline sequences (or veneers) to extend the branching range of the jump relocations.

Relocation R\_ARM\_THM\_JUMP6 is only applicable to the Thumb-2 instruction set.

Table 5.8: Table 4-13, Static Thumb-16 Relocations

Code	Name	Overflow	Instruction	Result Mask
7	R_ARM_THM_ABS5	Yes	LDR(1)/LDR(immediate, Thumb), STR(1)/STR(immediate, Thumb)	X & 0x7C
11	R_ARM_THM_PC8	Yes	LDR(3)/LDR(literal), ADD(5)/ADR	X & 0x3FC
52	R_ARM_THM_JUMP6	Yes	CBZ, CBNZ	X & 0x7E
102	R_ARM_THM_JUMP11	Yes	B(2)/B	X & 0xFFE
103	R_ARM_THM_JUMP8	Yes	B(1)/B <cond></cond>	X & 0x1FE
132	R_ARM_THM_ALU_ABS_G0_NC	No	ADD(2)/ADD (immediate, Thumb, 8-bit immediate), MOV(1)/MOV (immediate)	X & 0x000000FF
133	R_ARM_THM_ALU_ABS_G1_NC	No	ADD(2)/ADD (immediate, Thumb, 8-bit immediate), MOV(1)/MOV (immediate)	X & 0x0000FF00
134	R_ARM_THM_ALU_ABS_G2_NC	No	ADD(2)/ADD (immediate, Thumb, 8-bit immediate), MOV(1)/MOV (immediate)	X & 0x00FF0000
135	R_ARM_THM_ALU_ABS_G3	No	ADD(2)/ADD (immediate, Thumb, 8-bit immediate), MOV(1)/MOV (immediate)	X & 0xFF000000

#### **Static Thumb32 relocations**

Relocations for 32-bit Thumb instructions are shown in *Table 4-14, Static Thumb-32 instruction relocations* (page 37). With the exception of R\_ARM\_THM\_CALL, these relocations are only applicable to 32-bit Thumb instructions.

Table 5.9: Table 4-14, Static Thumb-32 instruction relocations

Code	Name	Overflow	Instruction	Result Mask
10	R_ARM_THM_CALL	Yes	BL	X & 0x01FFFFFE
30	R_ARM_THM_JUMP24	Yes	B.W	X & 0x01FFFFFE

			12-bit immediate	

The formation of the initial addend in a REL type relocation for the various instruction classes is described in *Table 4-15 Thumb relocation actions by instruction type* (page 38). Insn modification describes how the result X is written back to the instruction; Result\_Mask is the value of X after the masking operation described in *Table 4-13* (page 37) or *Table 4-14* (page 37) has been applied.

### Thumb call and jump relocations

R\_ARM\_THM\_CALL is used to relocate Thumb BL (and Armv5 Thumb BLX) instructions. It is the Thumb equivalent of R\_ARM\_CALL and the same rules on conversion apply. Bits 0-10 of the first half-word encode the most significant bits of the branch offset, bits 0-10 of the second half-word encode the least significant bits and the offset is in units of half-words. Thus 22 bits encode a branch offset of  $\pm$ 0 bytes. When linking Armv6 (and later, see [ARM ARM]) Thumb code the range of the branch is increased by 2 bits, increasing the offset range to  $\pm$ 0 bytes. The same relocation is used for both cases since a linker need only know that the code will run on a Thumb-2 (Armv6 and later) capable processor to exploit the additional range.

The addend for B.W and B<cond>.W is the signed immediate quantity encoded in the instruction, extracted in a similar way to BL; for details see [ARMARM<sup>19</sup>].

The conditions under which call and jump relocations are permitted to generate an ip-corrupting intracall veneer, and their behaviour in conjunction with unresolved weak references, are specified in *Static Arm relocations* (page 33) under the heading Call and Jump relocations.

<sup>19</sup> https://developer.arm.com/docs/ddi0406/c/arm-architecture-reference-manual-armv7-a-and-armv7-r-edition

#### Static miscellaneous relocations

R\_ARM\_NONE records that the section containing the place to be relocated depends on the section defining the symbol mentioned in the relocation directive in a way otherwise invisible to the static linker. The effect is to prevent removal of sections that might otherwise appear to be unused.

R\_ARM\_V4BX records the location of an Armv4t BX instruction. This enables a static linker to generate Armv4 compatible images from Armv4t objects containing only Arm code by converting the instruction to MOV PC, r, where r is the register used in the BX instruction. See [AAPCS] for details. The symbol is unused and may even be the NULL symbol (index 0).

R\_ARM\_TARGET1 is processed in a platform-specific manner. It may only be used in sections with the types SHT\_INIT\_ARRAY, SHT\_PREINIT\_ARRAY, and SHT\_FINI\_ARRAY. The relocation must be processed either in the same way as R\_ARM\_REL32 or as R\_ARM\_ABS32: a virtual platform must specify which method is used. If the relocation is processed as R\_ARM\_REL32 then the section may be marked read-only and coalesced with other read-only data, otherwise it may only be marked read-only if it does not require dynamic linking.

R\_ARM\_TARGET2 is processed in a platform-specific manner. It is used to encode a data dependency that will only be dereferenced by code in the run-time support library.

#### **Proxy generating relocations**

A number of relocations generate proxy locations that are then subject to dynamic relocation. The proxies are normally gathered together in a single table, called the Global Offset Table or GOT. *Table 4-16, Proxy generating relocations* (page 40) lists the relocations that generate proxy entries.

Code	Relocation	Comment	
26	R_ARM_GOT_BREL	Offset of the GOT entry relative to the GOT origin	
95	R_ARM_GOT_ABS	Absolute address of the GOT entry	
96	R_ARM_GOT_PREL	Offset of the GOT entry from the place	
97	R_ARM_GOT_BREL12	Offset of the GOT entry from the GOT origin. Stored in the offset	
		field of an Arm LDR instruction	
131	R_ARM_THM_GOT_BREL12	Offset of the GOT entry from the GOT origin. Stored in the offset	
		field of a Thumb LDR instruction	

Table 5.11: Table 4-16, Proxy generating relocations

All of the GOT entries generated by these relocations are subject to dynamic relocation by R\_ARM\_GLOB\_DAT of the symbol indicated in the generating relocation. There is no provision for generating an addend for the dynamic entry. GOT entries must always be 32-bit aligned words. Multiple GOT-generating relocations referencing the same symbol may share a single entry in the GOT.

R\_ARM\_GOT\_BREL, R\_ARM\_GOT\_BREL12 and R\_ARM\_THM\_GOT\_BREL12 generate an offset from the addressing origin of the GOT. To calculate the absolute address of an entry it is necessary to add in the GOT's addressing origin. How the origin is established depends on the execution environment and several relocations are provided in support of it.

- R\_ARM\_BASE\_PREL with the NULL symbol (symbol 0) will give the offset of the GOT origin from the address of the place.
- R\_ARM\_BASE\_ABS with the NULL symbol will give the absolute address of the GOT origin.
- Other execution environments may require that the GOT origin be congruent with some other base. In these environments the appropriate means of establishing that base will apply.

In addition to the data generating relocations listed above the call and branch relocations (R\_ARM\_CALL, R\_ARM\_THM\_CALL, R\_ARM\_JUMP24, R\_ARM\_THM\_JUMP24, R\_ARM\_THM\_JUMP19) may also require a proxy to be generated if the symbol will be defined in an external executable or may be preempted at execution time. The details of proxy sequences and locations are described in *PLT Sequences and Usage Models* (page 17).

R\_ARM\_GOTRELAX is reserved to permit future-linker based optimizations of GOT addressing sequences.

#### Relocations for thread-local storage

The static relocations needed to support thread-local storage in a SVr4-type environment are listed in *Table 4-17, Static TLS relocations* (page 41).

**Table 4-17, Static TLS relocations** 

Code	Relocation	Place	Comment
104	R_ARM_TLS_GD32	Data	General Dynamic Model
105	R_ARM_TLS_LDM32	Data	Local Dynamic Model
106	R_ARM_TLS_LDO32	Data	Local Dynamic Model
107	R_ARM_TLS_IE32	Data	Initial Exec Model
108	R_ARM_TLS_LE32	Data	Local Exec Model
109	R_ARM_TLS_LDO12	Arm LDR	Local Dynamic Model
110	R_ARM_TLS_LE12	Arm LDR	Local Exec Model
111	R_ARM_TLS_IE12GP	Arm LDR	Initial Exec Model

R\_ARM\_TLS\_GD32 causes two adjacent entries to be added to the dynamically relocated section (the Global Offset Table, or GOT). The first of these is dynamically relocated by R\_ARM\_TLS\_DTPMOD32, the second by R\_ARM\_TLS\_DTPOFF32. The place resolves to the offset of the first of the GOT entries from the place.

R\_ARM\_TLS\_LDM32 is the same as R\_ARM\_TLS\_GD32 except that the second slot in the GOT is initialized to zero and has no dynamic relocation.

R\_ARM\_TLS\_LDO32 resolves to the offset of the referenced data object (which must be local to the module) from the origin of the TLS block for the current module.

R\_ARM\_TLS\_LDO12 is the same as R\_ARM\_TLS\_LDO32 except that the result of the relocation is encoded as the 12-bit offset of an Arm LDR instruction.

R\_ARM\_TLS\_LE32 resolves to the offset of the referenced data object (which must be in the initial data block) from the thread pointer (\$tp).

R\_ARM\_TLS\_LE12 is the same as R\_ARM\_TLS\_LE32 except that the result of the relocation is encoded as the 12-bit offset of an Arm LDR instruction.

R\_ARM\_TLS\_IE32 allocates an entry in the GOT that is dynamically relocated by R\_ARM\_TLS\_TPOFF32. The place resolves to the offset of the GOT entry from the place.

R\_ARM\_TLS\_IE12GP allocates an entry in the GOT that is dynamically relocated by R\_ARM\_TLS\_TPOFF32. The place resolved to the offset of the GOT entry from the origin of the GOT and is encoded in the 12-bit offset of an Arm LDR instruction.

#### **New experimental TLS relocations**

http://www.lsd.ic.unicamp.br/~oliva/writeups/TLS/RFC-TLSDESC-ARM.txt contains a proposal for enhanced performance of TLS code. At this stage the proposal is still experimental, but the relocations R\_ARM\_TLS\_DESC, R\_ARM\_TLS\_GOTDESC, R\_ARM\_TLS\_CALL, R\_ARM\_TLS\_DESCSEQ, R\_ARM\_THM\_TLS\_CALL, R\_ARM\_THM\_TLS\_DESCSEQ16 and R\_ARM\_THM\_TLS\_DESCSEQ32 have been reserved to support this.

**Note:** The relocation R\_ARM\_TLS\_DESC re-uses relocation code from the now-obsolete R\_ARM\_SWI24, but since the former was a static relocation and the new relocation is dynamic there are no practical conflicts in usage.

#### **Dynamic relocations**

The dynamic relocations for those execution environments that support only a limited number of runtime relocation types are listed in *Table 4-18*, *Dynamic relocations* (page 42).

**Table 4-18, Dynamic relocations** 

Code	Relocation	Comment	
17	R_ARM_TLS_DTPMOD32	$(S \neq 0)$ Resolves to the module number of the module defining	
		the specified TLS symbol, S.	
		(S = 0) Resolves to the module number of the current module	
		(ie. the module containing this relocation).	
18	R_ARM_TLS_DTP0FF32	Resolves to the index of the specified TLS symbol within its TLS block	
19	R_ARM_TLS_TP0FF32	$(S \neq 0)$ Resolves to the offset of the specified TLS symbol, S, from	
		the Thread Pointer, TP.	
		(S = 0) Resolves to the offset of the current module's TLS block	
		from the Thread Pointer, TP (the addend contains the offset of	
		the local symbol within the TLS block).	
20	R_ARM_COPY	See below	
21	R_ARM_GLOB_DAT	Resolves to the address of the specified symbol	
22	R_ARM_JUMP_SLOT	Resolves to the address of the specified symbol	
23	R_ARM_RELATIVE	$(S \neq 0)$ B(S) resolves to the difference between the address at	
		which the segment defining the symbol S was loaded and the	
		address at which it was linked.	
		(S = 0) B(S) resolves to the difference between the address at	
		which the segment being relocated was loaded and the address	
		at which it was linked.	

With the exception of R\_ARM\_COPY all dynamic relocations require that the place being relocated is a word-aligned 32-bit object.

R\_ARM\_JUMP\_SLOT is used to mark code targets that will be executed. On platforms that support dynamic binding the relocations may be performed lazily on demand. The unresolved address stored in the place will initially point to the entry sequence stub for the dynamic linker and must be adjusted during initial loading by the offset of the load address of the segment from its link address. Addresses stored in the place of these relocations may not be used for pointer comparison until the relocation has been resolved. In a REL form of this relocation the addend, A, is always 0.

R\_ARM\_COPY may only appear in executable objects where e\_type is set to ET\_EXEC. The effect is to cause the dynamic linker to locate the target symbol in a shared library object and then to copy the number of bytes specified by the st\_size field to the place. The address of the place is then used to pre-empt all other references to the specified symbol. It is an error if the storage space allocated in the executable is insufficient to hold the full copy of the symbol. If the object being copied contains dynamic relocations then the effect must be as if those relocations were performed before the copy was made.

**Note:** R\_ARM\_COPY is normally only used in SVr4 type environments where the executable is not position independent and references by the code and read-only data sections cannot be relocated dynamically to refer to an object that is defined in a shared library.

The need for copy relocations can be avoided if a compiler generates all code references to such objects indirectly through a dynamically relocatable location, and if all static data references are placed in relocatable regions of the image. In practice, however, this is difficult to achieve without source-code annotation; a better approach is to avoid defining static global data in shared libraries.

#### **Deprecated relocations**

Deprecated relocations are in the process of being retired from the specification and may be removed or marked obsolete in future revisions. An object file containing these codes is still conforming, but producers should be changed to use the new alternatives.

The relocations R\_ARM\_GNU\_VTENTRY and R\_ARM\_GNU\_VTINHERIT have been used by some toolchains to facilitate unused virtual function elimination during linking. This method is not recommended and these relocations may be made obsolete in a future revision of this specification. These relocations may be safely ignored.

**Table 4-19, Deprecated relocations** 

Relocation	Replacement
R_ARM_PC24	Use R_ARM_CALL or R_ARM_JUMP24
R_ARM_PLT32	Use R_ARM_CALL or R_ARM_JUMP24
R_ARM_LDR_SBREL_11_0_NC	Use R_ARM_LDR_SB_Gxxx
R_ARM_ALU_SBREL_19_12_NC	Use R_ARM_ALU_SB_Gxxx
R_ARM_ALU_SBREL_27_20_CK	Use R_ARM_ALU_SB_Gxxx
R_ARM_SBREL31	Use new exception table format. Previous drafts of this document
	sometimes referred to this relocation as R_ARM_ROSEGREL32.
R_ARM_GNU_VTENTRY	None
R_ARM_GNU_VTINHERIT	None

#### **Obsolete relocations**

Obsolete relocations are no-longer used in this revision of the specification (but had defined meanings in a previous revision). Unlike deprecated relocations, there is no, or little known, use of these relocation codes. Conforming object producers must not generate these relocation codes and conforming linkers are not required to process them. Future revisions of this specification may re-assign these codes for a new relocation type.

#### **Private relocations**

Relocation types 112-127 and 161-176 are reserved as platform-specific relocations. The interpretation of these relocations is dependent on the value of the EI\_OSABI field of the ELF header. If the value of EI\_OSABI is zero or ELFOSABI\_ARM\_AEABI, these relocations are reserved.

#### **Army8.1-M Mainline Branch Future relocations**

R\_ARM\_THM\_BF16, R\_ARM\_THM\_BF12 and R\_ARM\_THM\_BF18 are used to relocate branch targets for the Branch Future instructions in Armv8.1-M Mainline. The formation of the initial addend in a REL type relocation for the various instruction classes is described in *Table 4-BFs-2 Armv8.1-M Mainline Branch Future relocation actions by instruction type* (page 44). The immediates mentioned in this table are the ones used to represent the offset from the targetted branch instruction to the branch target using a two's complement immediate. That is this immediate should be the same as the one being used by the targetted branch instruction. Insn modification describes how the result X is written back to

the instruction; Result\_Mask is the value of X after the masking operation described in *Table 4-BFs-1 Armv8.1-M Mainline Branch Future relocations* (page 44) has been applied.

In all cases the following semantics apply:

- A Branch Future to an out of range label must either be replaced with a NOP or re-use an existing trampoline that jumps to the relocation target, it must not create a new trampoline. (It is up to the implementation to decide which of these options is preferable).
- No errors are required.

Table 5.12: Table 4-BFs-1 Armv8.1-M Mainline Branch Future relocations

Code	Name	Overflow	Instruction	Result Mask
136	R_ARM_THM_BF16	Replace with NOP	BF 16-bit immediate	X & 0x0001FFFE
137	R_ARM_THM_BF12	Replace with NOP	BFCSEL 12-bit immediate	X & 0x00001FFE
138	R_ARM_THM_BF18	Replace with NOP	BFL 18-bit immediate	X & 0x0007FFFE

Table 5.13: Table 4-BFs-2 Armv8.1-M Mainline Branch Future relocation actions by instruction type

Instruction	REL Addend	Insn modification
BF (label, label)	insn[20:16] << 12   insn[10:1] << 2   insn[11] << 1   1	insn[10:1] = (Result_Mask(X) >> 2) & 0x000003FF insn[11] = (Result_Mask(X) >> 1) & 0x00000001 insn[20:16] = Result_Mask(X) >> 12

BFL (label, label)	insn[22:16] << 12   insn[10:1] << 2   insn[11] << 1   1	insn[10:1] = (Result_Mask(X) >> 2) & 0x000003FF insn[11] = (Result_Mask(X) >> 1) & 0x00000001 insn[22:16] = Result_Mask(X) >> 12

### **Unallocated relocations**

All unallocated relocation types are reserved for use by future revisions of this specification.

### 5.6.2 Idempotency

All RELA type relocations are idempotent. They may be reapplied to the place and the result will be the same. This allows a static linker to preserve full relocation information for an image by converting all REL type relocations into RELA type relocations.

**Note:** A REL type relocation can never be idempotent because the act of applying the relocation destroys the original addend.

### PROGRAM LOADING AND DYNAMIC LINKING

### 6.1 Introduction

This section provides details of Arm-specific definitions and changes relating to executable images.

# 6.2 Program Header

The Program Header provides a number of fields that assist in interpretation of the file. Most of these are specified in the base standard. The following fields have Arm-specific meanings.

#### p\_type

Table 5-1, Processor-specific segment types (page 46) lists the processor-specific segment types.

Table 5-1, Processor-specific segment types

Name	p_type	Meaning
PT_ARM_ARCHEXT	0x70000000	Platform architecture compatibility information
PT_ARM_EXIDX	0x70000001	Exception unwind tables
PT_ARM_UNWIND		

A segment of type PT\_ARM\_ARCHEXT contains information describing the platform capabilities required by the executable file. The segment is optional, but if present it must appear before segment of type PT\_LOAD. The platform independent parts of this segment are described in *Platform architecture compatibility data* (page 46).

PT\_ARM\_EXIDX (alias PT\_ARM\_UNWIND) describes the location of a program's unwind tables.

#### p\_flags

There are no processor-specific flags. All bits in the PT\_MASKPROC part of this field are reserved to future revisions of this specification.

### 6.2.1 Platform architecture compatibility data

This data describes the platform capabilities required by an executable file. It can be constructed by a linker using the attributes [ABI-addenda, addenda32-section2] found in its input relocatable files, or otherwise.

If this segment is present it shall contain at least one 32-bit word with meaning defined by *Table 5-2* (page 47), *Table 5-3* (page 47), *Table 5-4* (page 47), and *Table 5-5* (page 47).

Table 5-2, Common architecture compatibility data masks

Name	Value	Meaning		
PT_ARM_ARCHEXT_FMTMSK		Masks bits describing the format of data in sub-		
		sequent words. The masked value is described in		
		<i>Table 5-3</i> (page 47), below.		
PT_ARM_ARCHEXT_PROFMSK 0x00ff0000		Masks bits describing the architecture profile re-		
		quired by the executable. The masked value is		
		described in <i>Table 5-4</i> (page 47), below.		
PT_ARM_ARCHEXT_ARCHMSK	0x000000ff	Masks bits describing the base architecture re-		
		quired by the executable. The masked value is		
		described in <i>Table 5-5</i> (page 47), below.		

*Table 5-3, Architecture compatibility data formats* (page 47) lists the architecture compatibility data formats defined by this ABI. All other format identifiers are reserved to future revisions of this specification.

Table 5-3, Architecture compatibility data formats

Name	Value	Meaning	
PT_ARM_ARCHEXT_FMT_OS	0x00000000	There are no additional words of data. Howeve	
		if EF_OSABI is non-zero, the relevant	
		platform ABI may define additional data that fol-	
		lows the initial word.	
PT_ARM_ARCHEXT_FMT_ABI	0x01000000	Platform architecture compatibility data (ABI for-	
		<i>mat)</i> (page 48), below describes the format of the	
		following data words.	

*Table 5-4, Architecture profile compatibility data* (page 47), lists the values specifying the architectural profile needed by an executable file.

Table 5-4, Architecture profile compatibility data

Name	Value	Meaning
PT_ARM_ARCHEXT_PROF_NONE	0x00000000	The architecture has no profile variants, or
		the image has no profile-specific constraints
PT_ARM_ARCHEXT_PROF_ARM	0x00410000	The executable file requires the Application
	('A'<<16)	profile
PT_ARM_ARCHEXT_PROF_RT	0x00520000	The executable file requires the Real-Time
	('R'<<16)	profile
PT_ARM_ARCHEXT_PROF_MC	0x004D0000	The executable file requires the Microcon-
	('M'<<16)	troller profile
PT_ARM_ARCHEXT_PROF_CLASSIC	0x00530000	The executable file requires the 'classic' ('A'
	('S'<<16)	or 'R' profile) exception model.

*Table 5-5, Architecture version compatibility data* (page 47) defines the values that specify the minimum architecture version needed by this executable file. These values are identical to those of the Tag\_CPU\_arch attribute used in the attributes section [ABI-addenda, addenda32-section2] of a relocatable file.

Table 5-5, Architecture version compatibility data

Name	Value	Meaning the executable file needs (at least)	
PT_ARM_ARCHEXT_ARCH_UNKN	0x00	The needed architecture is unknown or specified	
		in some other way	
PT_ARM_ARCHEXT_ARCHv4	0x01	Architecture v4	
PT_ARM_ARCHEXT_ARCHv4T	0x02	Architecture v4T	
PT_ARM_ARCHEXT_ARCHv5T	0x03	Architecture v5T	
PT_ARM_ARCHEXT_ARCHv5TE	0x04	Architecture v5TE	
PT_ARM_ARCHEXT_ARCHv5TEJ	0x05	Architecture v5TEJ	
PT_ARM_ARCHEXT_ARCHv6	0x06	Architecture v6	
PT_ARM_ARCHEXT_ARCHv6KZ	0x07	Architecture v6KZ	
PT_ARM_ARCHEXT_ARCHv6T2	0x08	Architecture v6T2	
PT_ARM_ARCHEXT_ARCHv6K	0x09	Architecture v6K	
PT_ARM_ARCHEXT_ARCHv7	0x0A	Architecture v7 (in this case the architecture pro-	
		file may also be required to fully specify the	
		needed execution environment)	
PT_ARM_ARCHEXT_ARCHv6M	0x0B	Architecture v6M (e.g. Cortex-M0)	
PT_ARM_ARCHEXT_ARCHv6SM	0x0C	Architecture v6S-M (e.g. Cortex-M0)	
PT_ARM_ARCHEXT_ARCHv7EM	0x0D	Architecture v7E-M	

#### Platform architecture compatibility data (ABI format)

The status of this section is informative. It records a proposal that might be adopted.

The data following the word defined by *Platform architecture compatibility data* (page 46) consists of an array of 2-byte signed integers (starting at offset 4 in the architecture compatibility data segment) followed by a number of null-terminated byte strings (NTBS). The p\_filesz field of the segment header gives the total size in bytes of the architecture compatibility data.

The integer array maps the ABI public attribute tags [ABI-addenda, addenda32-section2] as follows.

- Array[0] contains the number of elements in array.
- If tag ≥ array[0], the value of tag for the executable file is 0. Only tags with non-0 values need to be mapped.
- If  $4 \le tag < array[0]$ , the value of tag for the executable file is array[tag]. A negative value v denotes that tag has the NTBS value found at offset –v from the start of the segment.
- Array[1] contains the major version number and array[2] the minor version number of the ABI release to which the data conforms (at least 2, 8). Array[3] is reserved and should be 0.

# 6.3 Program Loading

There are no processor-specific definitions relating to program loading.

# 6.4 Dynamic Linking

### 6.4.1 Dynamic Section

Table 5-6, Arm-specific dynamic array tags (page 48) lists the processor-specific dynamic array tags.

Table 5-6, Arm-specific dynamic array tags

Name	Value	d_un	Executable	Shared Object
DT_ARM_RESERVED1	0x70000000			
DT_ARM_SYMTABSZ	0x70000001	d_val	Platform specific	Platform specific
DT_ARM_PREEMPTMAP	0x70000002	d_ptr	Platform specific	Platform specific
DT_ARM_RESERVED2	0x70000003			

DT\_ARM\_SYMTABSZ gives the number of entries in the dynamic symbol table, including the initial dummy symbol.

DT\_ARM\_PREEMPTMAP holds the address of the pre-emption map for platforms that use the DLL static binding model. See *Symbol Pre-emption in DLLs* (page 16) for details. On platforms that permit use of a pre-emption map, the DT\_SONAME tag must be present in all shared objects.

**Note:** Some executable images may exist that use DT\_ARM\_RESERVED1 and DT\_ARM\_RESERVED2 instead of DT\_ARM\_SYMTABSZ and DT\_ARM\_PREEMPTMAP respectively. These tags use the d\_un field in a manner incompatible with the Generic ELF requirements.

## 6.5 Post-Link Processing

For some execution environments a further processing step may be needed after linking before an executable can be run on the target environment. The precise processing may depend on both the target platform. Depending on the nature of the post-processing it may be done in any of following places

- As a final step during linking
- As a preliminary step during execution of the image
- As a separate post-linking step

In some cases the result may still be an ELF executable image, in others it may produce an image that is in some other format more appropriate to the operating system.

## 6.5.1 Production of BE-8 images

Images that are expected to execute in big-endian mode on processors that implement Architecture version 6 or higher will normally need to be post-processed to convert the instructions that are in big-endian byte order to little-endian as expected by the processor. The mapping symbol information can be used to do this transformation accurately. In all segments that contain executable code:

- For areas mapped as data (\$d or \$d.<any...>) no changes are made
- For areas mapped as Thumb (\$t or \$t.<any...>) each half-word aligned pair of bytes are swapped
- For areas mapped as Arm (\$a or \$a.<any...>) each word-aligned object is swapped so that the first and fourth bytes are exchanged and the second and third exchanged.

An ELF image that has been transformed in this manner is marked by setting EF\_ARM\_BE8 in the e\_flags field.

**Note:** If BE-8 images are subject to further relocation of instructions (either by a dynamic linker or by further post-linking operations) account must be taken of the fact that the instructions are now in little-endian format.

CHAPTER

**SEVEN** 

## APPENDIX SPECIMEN CODE FOR PLT SEQUENCES

The status of this appendix is informative.

## 7.1 DLL-like, single address space, PLT linkage

The simplest code sequence for the PLT entry corresponding to imported symbol X is:

```
LDR ip, [pc, #0] ; Load the 32-bit offset of my PLTGOT entry from SB

LDR pc, [ip, sb]! ; Branch indirect through the PLTGOT entry leaving ip addressing the

--PLTGOT slot

DCD R_ARM_GOT_BREL(X) ; GOT_BASE = SB
```

The final DCD is subject to relocation by a PLTGOT-generating relocation directive. This directive may be processed by a target-specific linker or by a target-specific post-linker. After processing:

- The place contains the 32-bit offset from the static base (sb) of the PLTGOT entry for X.
- The PLTGOT entry for X is subject to an R ARM JUMP SLOT(X) dynamic relocation.

A more complicated sequence that avoids one of the memory accesses is:

```
ADD ip, sb, #:SB_OFFSET_27_20:__PLTGOT(X) ; R_ARM_ALU_SB_G0_NC(__PLTGOT(X))
ADD ip, ip, #:SB_OFFSET_19_12:__PLTGOT(X) ; R_ARM_ALU_SB_G1_NC(__PLTGOT(X))
LDR pc, [ip, #:SB_OFFSET_11_0:__PLTGOT(X)]! ; R_ARM_LDR_SB_G2(__PLTGOT(X))
```

If the linker can place all PLTGOT entries within 1MB of SB, the sequence becomes:

```
ADD ip, sb, #:SB_OFFSET_19_12:__PLTGOT(X) ; R_ARM_ALU_SB_G0_NC(__PLTGOT(X))
LDR pc, [ip, #:SB_OFFSET_11_0:__PLTGOT(X)]! ; R_ARM_LDR_SB_G1(__PLTGOT(X))
```

The write-back on the final LDR ensures that ip contains the address of the PLTGOT entry. This is critical to incremental dynamic linking.

# 7.2 DLL-like, multiple virtual address space, PLT linkage

The code sequence for the PLT entry corresponding to imported symbol X is:

```
LDR ip, [pc, #0] ; Load the 32-bit address of my PLTGOT entry
LDR pc, [ip] ; Branch indirect through the PLTGOT entry
DCD R_ARM_GOT_ABS(X) ; GOT_BASE = 0
```

Note that ip addresses the PLTGOT entry, which is critical to incremental dynamic linking.

The final DCD is subject to relocation by a PLTGOT-generating relocation directive. This directive may be processed by a target-specific linker or by a target-specific post-linker. After processing:

• The place contains the 32-bit address of the PLTGOT entry for X.

• The PLTGOT entry for X is subject to an R ARM JUMP SLOT(X) dynamic relocation.

Because a DLL has two segments that can be loaded independently, there is no more efficient address generating sequence – analogous to the SB-relative sequence shown in above – that does not require complex instruction field-relocating directives to be processed at dynamic link time.

This ABI requires dynamic relocations to relocate 32-bit fields, so there is no sequence analogous to that of the preceding subsection.

## 7.3 SVr4 DSO-like PLT linkage

The simplest code sequence for the PLT entry corresponding to imported symbol X is:

```
LDR ip, L2 ; Load the 32-bit pc-relative offset of my PLTGOT entry
L1: ADD ip, ip, pc ; formulate its address...
LDR pc, [ip] ; Branch through the PLTGOT entry addressed by ip
L2: DCD R_ARM_GOT_PREL(X) + (L2 L1 8)
```

The dynamic linker relies on ip addressing the PLTGOT entry for X.

The final DCD is subject to static relocation by a PLTGOT-generating relocation directive. This directive may be processed by a target-specific linker or by a target-specific post-linker. After processing:

- The place contains the 32-bit offset from L1+8 to the PLTGOT entry for X.
- The PLTGOT entry for X is subject to an R ARM JUMP SLOT(X) dynamic relocation.

A more complicated, pc-relative, sequence that avoids one of the memory accesses is shown below. Because an SVr4 executable file is compact (usually  $< 2^{28}$  bytes) and rigid (it has only one base address, whereas a DLL has two), all the relocations can be fully resolved during static linking.

```
ADD ip, pc, #-8:PC_OFFSET_27_20: __PLTGOT(X) ; R_ARM_ALU_PC_G0_NC(__PLTGOT(X))

ADD ip, ip, #-4:PC_OFFSET_19_12: __PLTGOT(X) ; R_ARM_ALU_PC_G1_NC(__PLTGOT(X))

LDR pc, [ip, #0:PC_OFFSET_11_0: __PLTGOT(X)]! ; R_ARM_LDR_PC_G2(__PLTGOT(X))
```

The write-back on the final LDR ensures that ip contains the address of the PLTGOT entry. This is critical to incremental dynamic linking.

In effect, the sequence constructs a 28-bit offset for the LDR. The first relocation does the right thing because pc addresses the LDR, so, in general, it picks out bits [27-20] of that offset. The third relocation picks out bits [11-0] of the same offset. The second relocation needs to construct bits [19-12] of the offset from dot+4 to X., that is, from dot to X-4. Ignoring the -4 sometimes produces the wrong answer!

Encoding such a small addend requires that the initial value not be shifted by the shift applied to the result value. This is expected for a RELA-type relocation that can encode -4 directly. However, a REL-type must encode the initial value of the addend using SUB ip, ip, #4.

In small enough DSOs ( $< 2^{20}$  bytes from the PLT to the PLTGOT) the first instruction can be omitted, and the sequence collapses to the following.

```
SUB ip, pc, #4:PC_OFFSET_19_12: __PLTGOT(X) ; R_ARM_ALU_PC_G0_NC(__PLTGOT(X))
LDR pc, [ip, #0:PC_OFFSET_11_0: __PLTGOT(X)]! ; R_ARM_LDR_PC_G2(__PLTGOT(X))
```

# 7.4 SVr4 executable-like PLT linkage

An SVr4 executable does not need be position independent, its writable segment can be relocated dynamically, and it is compact and rigid. Therefore, its PLT entries can use the simple, absolute code sketched in *DLL-like, multiple virtual address space, PLT linkage* (page 50) or the more complex, pc-relative, versions sketched in *SVr4 DSO-like PLT linkage* (page 51), as the tool chain chooses.

In both cases, ip must address the corresponding PLTGOT slot at the point where the PLT calls through it.

**CHAPTER** 

**EIGHT** 

## **CONVENTIONS FOR SYMBOLS CONTAINING \$**

The status of this appendix is informative.

A toolchain is not required to support any of the conventions described in this appendix; however, it is recommended that if symbols matching the patterns described are used, then the following conventions are adhered to.

## 8.1 Base, Length and Limit symbols

A number of symbols may be used to delimit the addresses and sizes of aspects of a linked image. These symbols are of the following general forms:

```
Load$$region_name$$Base
Image$$region_name$${Base|Length|Limit}
Image$$region_name$$ZI$${Base|Length|Limit}
Image$${RO|RW|ZI}$${Base|Limit}
SectionName$${Base|Limit}
```

A toolchain may define these symbols unconditionally, or only if they are referred to by the application: so a post-linker must not depend on the existence of any of these symbols.

# 8.2 Sub-class and Super-class Symbols

A symbol \$Sub\$\$name is the sub-class version of name. A symbol \$Super\$\$name is the super-class version of name. In the presence of a definition of both name and \$Sub\$\$name:

- A reference to name resolves to the definition of \$Sub\$\$name.
- A reference to \$Super\$\$name resolves to the definition of name.

It is an error to refer to \$Sub\$\$name, or to define \$Super\$\$name, or to use \$Sub\$\$... or \$Super\$\$... recursively.

# 8.3 Symbols for Veneering and Interworking Stubs

A veneer symbol has the same binding as the symbol it veneers. They are used to label sequences of instructions that are automatically generated during linking. The general format of the symbols is:

```
${Ven|other}${AA|AT|TA|TT}${I|L|S}[$PI]$$symbol_name
```

where AA, AT, TA, or TT denotes the type of the veneer — Arm to Arm, Arm to Thumb, etc; I, L, or S denotes inline (the target follows immediately), long reach (32-bit), or short reach (typically 26-bit); and \$PI denotes that the veneer is position independent.
